## SAGA API Bindings: Python

### Status of This Document

This document informs implementors of the SAGA API in the Python programming language, and acts as syntactic and semantic reference. Distribution of this document is unlimited.

### Abstract

This document provides information to the grid community, proposing a standard for a Python language binding to the Simple API for Grid Applications (SAGA). As a SAGA language binding, it depends upon the SAGA Core API Specification [6], the currently defined SAGA API extension packages [7, 8, 4, 5], and on the draft Resource API Extension [9].

# 1 Introduction

## 1.1 Notational Conventions

In structure, notation and conventions, this documents follows those of the SAGA Core API specification [6], unless noted otherwise.

## 1.2 Security Considerations

As the SAGA API is to be implemented on different types of Grid (and non-Grid) middleware, it does not specify a single security model, but rather provides hooks to interface to various security models – see the documentation of the `saga::context` class in the SAGA Core API specification [6] for details.

A SAGA implementation is considered secure if and only if it fully supports (i.e. implements) the security models of the middleware layers it builds upon, and neither provides any (intentional or unintentional) means to by-pass these security models, nor weakens these security models' policies in any way.

## 2 SAGA Python Bindings

This section will motivate and discuss the general design principles for the SAGA Python bindings. That results in a set of rules which prescribe the translation of the SAGA API as specified in GFD.90 and in the SAGA API Extension specification documents. Those rules SHOULD also be applied to future SAGA API extensions.

The explicit python bindings are listed in appendix A.

### 2.1 Python Version

This language binding specification targets Python version 2.x and 3.x. We do not expect implementations to support that whole range of versions – but the bindings themselves should not be a limiting factor in that respect.

### 2.2 Class Hierarchy Considerations

As for other language bindings (i.e. C++, Java), the package names will not be part of the module hierarchy for the SAGA Core Look & Feel classes. For functional API packages, the package name is part of the module path: i.e., `saga.Context` instead of `saga.context.Context`, but `saga.job.Service` instead of `saga.JobService`.

The SAGA API defines an interface and class hierarchy which is normally followed by language bindings. For Python, a strict adherence to that hierarchy is neither required nor useful: Python's duck-typing paradigm [1] encourages the flattening of inherited base classes into the actual object implementations. The paragraphs below discuss the cases where this is used in the SAGA Python bindings.

#### 2.2.1 SAGA Object Interface

Most SAGA classes as specified in GFD.90 inherit from the base `saga.object` class. That class provides a unique object ID for class instances, deep copy semantics, object type inspection and access to the `saga.session` instance which manages that object.

Python provides most of these facilities natively: it has type inspection and unique object IDs, and the core python library comes with a generic deep copy call. The python bindings are thus not expected to implement the `saga.object`

class, but MAY attach the remaining `get_session()` method directly to the respective object types (for reasons discussed later, the session will also be exposed as an object property). Instead, all SAGA objects MUST (directly or indirectly inherit from Python's base `object` class, and are thus rendered as *'new style'* classes [2].

### 2.2.2 SAGA Namespace Package

The GFD.90 'namespace' package defines a common interface for several downstream packages which, amongst others, interface to entities organized in namespaces, such as physical files, logical files (replicas), information services, etc. The namespace package thus functions as an interface package, and implementations MAY flatten it into the respective deriving class implementations. While that would not allow the direct instantiation namespace class entities, Python's duck typing and loose type system would still allow the use of interchangeable derivatives.

### 2.2.3 SAGA Buffer Class

The `saga.Buffer` class of GFD.90 is used for a variety of I/O operations, on streams, files, messages, RPC-calls etc. Its primary purpose (as opposed to using plain data arrays) is to support both implementation and user managed memory segments, and thus to support zero copy implementations for I/O operations.

Python applications traditionally tend not to interfere with Python level memory management – for example, zero copy implementations are not a first level concern. The Python bindings thus do not define a separate `buffer` class – they instead use strings (which can contain encoded data). This also holds for classes which would normally inherit from `saga.Buffer`, e.g for the `rpc.Parameter` and `message.Message` classes.

## 2.3 SAGA Attributes and Python Properties

Python's native way to express class attributes is to expose them as class or object properties. The SAGA Python bindings follow that model. SAGA Attributes have, however, a slightly different semantic in most cases: they do not represent attributes of the local application class instance, but mostly properties of remote entities that these class instances represent. In that context, it must be noted that they:

- cannot be accessed via asynchronous operations,

- cannot be monitored via callbacks,
- cannot be inspected for vector / scalar types,
- cannot be listed (directly),
- may not be extensible (unlike in python proper).

For those reasons, a GFD.90-like attribute interface is also provided in Python. Following similar arguments, the property interface is also provided as complement to various `get_xyz()` methods (readonly), and to `get_xyz()/set_xyz()` pairs (read/write). Finally, the property interface is in some cases used to expose local object state in general. For example, a `saga.Session` object will expose a `contexts` property, a list whose manipulation maps to the default `add_context()/remove_context()` methods.

Another way to expose attributes in Python is the dict(ionary) interface. Compared to the property interface, a dict additionally allows inspection of and iteration over attribute keys. Despite that additionally exposed semantics (which maps well to the GFD.90 attribute semantics), the SAGA Python bindings will not be expressed via the dict interface, to keep the binding focused and simple.

As in GFD.90, attribute and metric names are specified in ‘CamelCase’. As per Python convention [3], property names are changed to ‘`under_score`’ notation.

## 2.4 Additional Python Properties

Appendix A specifies explicitly where getter and setter functions are mapped to python properties, in the following notation:

```
host = property (get_host, set_host)
```

In cases where properties are used to manage sets of components, we map setter, getter and list-like methods to a mutable property list:

---

```
s = saga.Session (...)  
c1 = saga.Context (...)  
c2 = saga.Context (...)  
  
s.add_context (c1)  
s.add_context (c2)  
  
for c_id in s.list_contexts () :  
    c = s.get_context (id)  
    print c.type
```

---

is then equivalent to:

---

```
s = saga.Session (...)

s.contexts.append (saga.Context (...))
s.contexts.append (saga.Context (...))

for c in s.contexts :
    print c.type
```

---

The informal notation for that case as used in Appendix A is:

```
contexts = property (...) # mutable list [saga.Contexts]
```

## 2.5 Attribute Value Types

GFD.90 defines the attribute value types, but explicitly maps those to strings. As Python provides flexible and transparent means of type conversion, the Python bindings support natively typed attribute values.

The `saga.job.Description`'s `Environment` attribute is typed as list of strings, where the strings are formatted as "key=value". Additionally, the Python bindings allow to express that attribute's value as a python dictionary.

## 2.6 Enums and Defines

The SAGA API includes a number of enums, which are usually related to classes within a specific API package. Python does not have a native notion of enums. We follow the recommendation in [3] to define constants on a module level, written in all capital letters with underscores separating words.

Further, GFD.90 recommends bindings to define constants expressions for pre-defined attribute and metric names. Those are also defined as module variables.

Note that module variables (enums and string defines) are in all `UPPER_CASE`, as suggested by [3].

## 2.7 Callbacks and Callables

Python is relatively flexible in passing, managing and invoking function pointers. In particular, it is rather easy to express callbacks in Python – the user simply passes a Python `callable` with a matching method signature, and this is getting called as needed. At this point it does not matter if the passed entity is a proper method, an object instance, or anything else – as long as it can be called.

The Python language binding adheres to GFD.90, and introduces a `Callback` class, which can be inherited and passed to watch monitorable metrics. But at the same time, that class is actually a callable (it implements `__call__`), and applications can thus pass any other callable just as well, including proper python methods, class member methods, etc.

### 2.7.1 Shallow versus Deep Copy

The SAGA specification prescribes shallow copy behaviour by default, and deep copy is available as an explicit function call. That reflects the default semantics in Python, where assignments are shallow copies by default. Unless a deep copy is explicitly required by the SAGA specification (for example when passing a job description), implementations **MUST** provide the default Python behaviour.

## 3 Intellectual Property Issues

### 3.1 Contributors

This document is the result of the joint efforts of many contributors. The author listed here and on the title page is the one taking responsibility for the content of the document, and all errors. The editor (underlined) is committed to taking permanent stewardship for this document and can be contacted in the future for inquiries.

## A Python Binding as Interface Code

This appendix contains the normative Python Bindings, as Python source code. Any Python implementation of SAGA SHOULD define this and only this interface. Note that Python does not allow specification of method return types, nor does it enforce types in the first place. The return types for methods are given as comments, and MUST be respected by the implementation.
